

# AOARD REPORT

Daido Steel's Shibukawa Plant, Shibukawa City, Gumma  
Prefecture, Japan, 29 Jul 94

29 Jul 1994  
P. McQuay  
AOARD

Daido Steel is the largest specialty steel maker in the world, and therefore has a strong interest in aerospace materials, such as heat and corrosion resistant steels, and Ti and Ni-based alloys. Daido Steel features some of the most advanced melting and processing equipment and practices available, and appears to be constantly upgrading their facilities and capabilities. Daido Steel has recently designed and is now testing an in-house developed unique spin forming press, designated the SRH, for Spinning and Rolling - Hot. This unique press allows for complex case and ring production in a single work piece, with the ability to produce both variable diameter and thickness with good precision. Additionally, utilizing it's high speed rotary forge, the Shibukawa Plant has unique capabilities for producing very large turbine shafts economically. Several Ti alloy/part development programs currently underway are also reviewed.

## 2. OVERVIEW AND BACKGROUND

Daido Steel, founded in 1916, is the largest specialty steel producer in Japan and the world. In fact, Daido claims to have approximately 90% of the specialty steel market in Japan. Total sales for 92 were \$2.51B, slightly off from 91 sales of \$2.73B. The largest customer for their products is the automobile industry (35%), and as such, they are currently experiencing difficulty economic times.

In total, Daido Steel has nine plants located at seven works which specialize in the following products:

- Shibukawa Plant: Rolled and forged steels
- Takakura Works and Fabricated Steel Products Plant: Industrial furnaces, robots, anti-pollution facilities, automotive parts and aircraft parts
- Chita Plant and Chita Steel Strip Plant: Rolled steels, hoop steels and die-forged steels
- Oji Plant: Hoop steel products
- Tsukiji Plant: Cast steels, magnetic products, and powdered alloys
- Hoshizaki Plant: Rolled steels
- Kawasaki Plant: Rolled steels

A brief profile of the activity of the Hoshizaki Plant is given in AOARD TR-94-15. Daido Steel also operates a Central Research Laboratory, which is located in Nagoya.

The Shibukawa Plant, which opened in 1937, is located in Shibukawa City, Gumma Prefecture, about 100 km North of Tokyo. It is a rural and very picturesque area known for it's skiing, hiking and hot spring resorts, which are located in the nearby mountains.

The monthly output capacity of the Shibukawa Plant is approximately 6,500 tons (metric) of forgings, 3,000 tons of rolled bars, and 1,500 tons of billets. The main products from the plant include component parts or materials for aircraft engines, chemical plants, power stations, iron and steel industry, shipbuilding, and tools.

## 3. DISCUSSIONS AND PLANT TOUR

This visit was arranged upon request of Dr. Fujishiro, AOARD/CC, whom I accompanied. The main purpose of the visit was to see a new experimental hot spinning mill, which will be described later.

Our primary host for the discussions and tour was:

Mr. Hiroh Inamori  
General Manager, Shibukawa Plant  
500 Ishihara  
Shibukawa, Gunma  
Japan  
Tel: +81 (279) 25-2001; Fax: +81 (279) 25-2040

Following introductions, we were given an outline of the production process of rolled and forged bar at the plant. Typical of a specialty steel producer, the starting material for the production of specialty steel is steel scrap. Both continuous and batch type processes are used, depending on the quantity of material to be produced, and the product form.

Attachment one contains a listing of the major manufacturing equipment (furnaces, presses, rolling mills, etc.) which are utilized at the Shibukawa Plant. The plant operates six

Vacuum Arc Remelting(VAR) and Electro-Slag Remelting (ESR) Furnaces each, of various sizes, the largest in each case being a 10 ton furnace. One of the VAR furnaces has been converted into an experimental hybrid VAR-ESR furnace, named a VSR for Vacuum-Slag Remelting Furnace. The experimental furnace is being used to examine the feasibility of creating a single process using the best features of both furnace technologies.

Although not at the Shibukawa Plant, Daido's Hoshizaki Plant (see AOARD TR-94-15) operates a unique Plasma Progressive Casting (PPC) unit. This unit gives Daido Steel a unique plasma-based melting technology for melting a combination of sponge and scrap Ti, and master alloys. A schematic and several additional fact sheets for the PPC unit is given in attachment two.

Although the overwhelming majority of it's business is specialty steel, Daido also produces superalloys, and Ti and Ti alloys. The main aero-engine products of the Shibukawa Plant are shafts and disks.

In the area of forging, the plant has an NFP Forging Machine (GFM-SXP55) which is a kind of rotary hammer forge which operates at very high speed and can produce cylindrical components to a rough product shape. This process can dramatically reduce the time and cost associated with producing a worked cylindrical bar piece for applications such as large shafts. They also have conventional hydraulic presses of 3500, 2600, and 1500 ton capacities.

From 1985 to 1993, Daido Steel has produced a total of 1300 turbo-engine shafts. The first mass-produced commercial shafts were produced for the V2500, and subsequently, shafts have been produced for the PW 2037 and 4056, the JT9D, and the GE 90. Daido is currently working on a new shaft development program with IHI and Rolls-Royce, presumably for the Trent engine program.

It is interesting to note that prior to Daido's entrance into the aero-engine shaft business, Daido enjoyed the development support of the Japanese government on at least four separate engine development programs to produce shafts, from 1975 to 1983. These programs were for titanium, steel and nickel-base superalloy shafts.

Through an affiliated company, the plant has access to numerous ring rolling mills for producing cases for aerojet and rocket engines. However, the pride and joy of Daido's processing equipment is an experimental spin forming machine, oddly named the SRH, for Spinning and Rolling - Hot. This in-house developed machine provides a unique capability to produce complex single-piece case structures, with variable diameters and an impressive ability to produce risers and complex cross-sections. The minimum and maximum ring or case diameters are 200-1600 mm. The maximum width of the base material is 150 mm, while the maximum for the finished part is 450 mm. The minimum thicknesses for the base material and product are 30 mm and 1.5 mm, respectively.

The unique design features of the SRH unit enable the production of a single ring or case with variable thickness, as well as diameter. It has much more flexibility and capability compared to a conventional ring-rolling mill. It can produce a heavily reduced complex part with near net shape detail in less than 30 minutes. Another unique feature is a built in induction heater, which heats the workpiece as it spins, opposite the tool. Reportedly the induction heater has a maximum workpiece temperature of up to 1200°C.

The unit has been in a test program for over a year. Most of the preliminary work has been accomplished on steel, but the unit is also envisioned to produce Ti, and Ni-based alloy parts. Attachment three contains a schematic and additional specifications of the SRH unit.

The Shibukawa plant is currently involved in several Ti alloy prototype programs. The first program is to develop a commercially successful Japanese disk alloy in collaboration with IHI. The two year program began in 1993, and is being sponsored by the Japan Aerospace Industrial Association. In particular, one of the main goals of the program is to develop a dual property disk alloy, where the mechanical properties at the rim and the bore of the disk are different.

The program alloy is called RNT101, and is considered a near beta alloy, with the following composition: Ti-5.7Al-4.0Sn-3.4Zr-3.0Mo-0.7Nb-0.3Si-0.06C. The alloy bears an obvious resemblance to IMI834, with the largest variation being the decrease in Zr and the increase in Mo. The increase in Mo was to boost the creep resistance (time to 0.5% creep strain at 600°C and 200 Mpa). Several of the technical challenges involved were melting practices and hot working practices to produce homogeneous material. In the case of melting a combination of PPC plus double VAR was used successfully. The ingot breakdown was performed using the GFM to minimize the heat loss and maximize the amount of uniform hot work.

Following the ingot breakdown, pancakes were two step forged, first beta and then alpha plus beta forged, and subsequently heat treated to two microstructural conditions: a beta anneal which produced a transformed beta microstructure, and an alpha plus beta anneal which produced a duplex microstructure. The results of the mechanical properties demonstrated that both microstructures have higher room and elevated temperature strength than IMI834, that the low cycle fatigue behavior is comparable, and that the creep resistance of the alpha plus beta anneal material is superior to IMI834. Future plans are to continue the microstructure/ property development of the alloy, and a manufacturing trial for a full-scale disk prototype with a dual property heat treatment.

The second development program Daido is working on is aimed at the production of forged Ti-17 disks, using the GE specification C50TF57 as a baseline for their property goals. The initial small scale prototype disk was reportedly a success, in terms of producing the part shape with no defects, achieving the desired microstructure, and achieving the property goals. A follow-on program is now under way to develop a full scale disk prototype.

Additional information regarding most of the above subjects is available upon request.

#### 4. SUMMARY AND COMMENTS

Daido features some of the most advanced melting and processing equipment and practices available, and appears to be constantly upgrading their facilities and capabilities. Clearly, the SRH unit provides a very unique capability to produce complex wrought cases and rings, while reducing processing steps, part counts and welding and joining issues.

Daido's entrance into aero-engine shaft business through government support is probably indicative of their future attempts to become a player in the aero-engine part manufacturing business. The next target of opportunity appears to be in the manufacture of disks. They appear to have the expertise, technology and determination to become a major player worldwide.
